

PART 4 CRUISE

◀ LIST OF FIGURES (F Mk.3 aircraft - white leaves)

4.1 Fuel conversion chart - lb/min/ \sqrt{t} to lb/min

Subsonic

With 250-gal ventral tank

- 4.2 Specific air range and fuel flow
 4.3 Specific air range and fuel flow - one engine windmilling
 4.4 Range profile at 30,000 ft
 4.5 Range profile at 36,000 ft

With 250-gal ventral tank and two Red Tops

- 4.6 Specific air range and fuel flow
 4.7 Specific air range and fuel flow - one engine windmilling
 4.8 Range profile at 30,000 ft
 4.9 Range profile at 36,000 ft

Supersonic

With 250-gal ventral tank

- 4.10 Specific air range - without reheat
 4.11 Specific air range - with reheat
 4.12 Fuel flow - without reheat
 4.13 Fuel flow - with reheat

With 250-gal ventral tank and two Red Tops

- 4.14 Specific air range - without reheat
 4.15 Specific air range - with reheat
 4.16 Fuel flow - without reheat
 4.17 Fuel flow - with reheat
 4.18 Specific air range and fuel flow - low altitude

LIST OF FIGURES (T Mk.5 aircraft - coloured leaves)

Subsonic

With 250-gal ventral tank

- 4.1 Specific air range and fuel flow
 4.2 Specific air range and fuel flow - one engine windmilling
 4.3 Range profile at 30,000 ft
 4.4 Range profile at 36,000 ft

With 250-gal ventral tank and two Red Tops

- 4.5 Specific air range and fuel flow
 4.6 Specific air range and fuel flow - one engine windmilling
 4.7 Range profile at 30,000 ft
 4.8 Range profile at 36,000 ft

Supersonic

With 250-gal ventral tank

- 4.9 Specific air range and fuel flow - low altitude
 4.10 Specific air range and fuel flow - without reheat
 4.11 Specific air range - with reheat
 4.12 Fuel flow - with reheat

With 250-gal ventral tank and two Red Tops

- 4.13 Specific air range and fuel flow - low altitude
 4.14 Specific air range and fuel flow - without reheat
 4.15 Specific air range - with reheat
 4.16 Fuel flow - with reheat ▶

1. Temperature correction

- (a) When flying at constant M and constant altimeter height the fuel flow (*lb/min*) is increased at high OAT and decreased at low OAT (*being in fact proportional to \sqrt{t}*).

A plot of $\text{lb/min} / \sqrt{t}$ against M and altimeter height is therefore correct for both standard and non-standard temperature conditions.

Fig. 4.1 gives the conversion from $\text{lb/min} / \sqrt{t}$ to lb/min over a range of temperatures.

Example:-

If $\text{lb/min} / \sqrt{t} = 460$

then, from Fig. 4.1.

$\text{lb/min} = 380$ at -76.5°C

- (b) $\text{anm}/100 \text{ lb}$ is independent of OAT at constant M and constant altimeter height and no correction for temperature is required. It follows that total distance gone in level flight for the consumption of a given amount of fuel is unaffected by OAT.

2. Flight profiles

- (a) The range charts are presented as continuous sorties, fuel being allowed for start up and taxi (450 *lb*), take-off (210 *lb*), acceleration to climb speed (240 *lb*), descent (900 *lb* Mk.3 aircraft, 1,000 *lb* Mk.5) and landing (1,600 *lb*). The fuel for the climb is estimated from the data of Part 3. Range is credited for climb (at 450 *kts*/0.87M) but not for the descent.

- (b) These profiles apply, strictly, to standard conditions only since the climb performance and, therefore, the amount of fuel available for cruising

varies with OAT. Since, however, the climb fuel is small compared with the cruise fuel, the effect of OAT will be small. For cruising heights above 36,000 ft the effect will, of course, be greater.

- (c) The range profiles are plotted as distance-to-go against fuel available. Each chart gives the range for various subsonic cruising speeds, including the optimum.

3. Supersonic cruise

Fig. 4.10 - 4.17 give the supersonic values of $\text{anm}/100 \text{ lb}$ and $\text{lb/min} / \sqrt{t}$ as a carpet graph in terms of M and altimeter height for a given mean cruise weight both with and without reheat. The 650 kt IAS line is also shown. Boundaries are plotted across the no reheat carpet for (maximum) 100% RPM/790°C JPT for five values of OAT, -36.5°C , -46.5°C , -56.5°C , -66.5°C and -76.5°C in green. All points lying to the right of any boundary are outside, those lying to the left are inside, this engine limit. On the reheat carpet boundaries are plotted in red for minimum reheat (1300°K), 100% RPM/790°C JPT for four values of OAT, -36.5°C , -46.5°C , -56.5°C and -66.5°C . Maximum reheat (1600°K), 100% RPM/790°C JPT for OAT of -36.5°C is shown in blue; lower OAT's are beyond the limits of the carpet.

Example (A)

Find the supersonic cruise data for the aircraft with 250-gal ventral tank at 36,000 ft and 1.2M at -56.5°C .

From Fig. 4.10.

This flight condition is inside the maximum engine setting without reheat, and $\text{anm}/100 \text{ lb} = 5.45$.

From Fig. 4.12

$\text{lb/min} / \sqrt{t} = 240$

From Fig. 4.1

The lb/min corrected for temperature = 210

Example (B)

Find the supersonic cruise data for the aircraft with 250-gal ventral tank and two Red Tops at 30,000 ft and 1.5M at -56.5°C.

From Fig. 4.14

This flight condition is outside the maximum engine setting without reheat.

From Fig. 4.15

anm/100 lb = 2.98

From Fig. 4.17

lb/min / \sqrt{t} = 550

From Fig. 4.1

The lb/min corrected for temperature = 478

Note...

- (1) *The cruise fuel consumption has been increased by 5% in all the Figures to allow for variations between aircraft.*
- (2) *The effect of the flight refuelling probe should be taken as one quarter of the difference due to missiles.*
